Nexus between Remittances and Economic Growth in Pacific Island Countries: A Study of Samoa

**T. K. Jayaraman

Ronald Kumar**

Abstract

Remittances have been a great support to Pacific island countries (PICs). Aside from providing additions to domestic savings and hence real resources, they have been one of the major sources of foreign exchange earnings. In the context of falling exports and limited options to diversify their exports, inward remittances have assumed greater importance. This paper examines the nexus between growth and remittances in Samoa.

I. INTRODUCTION

The first round effects of the financial crisis in the late 2007 in the United States (US), which spread to other advanced countries due to their exposure to the US mortgage backed securities, spared the Pacific island countries (PICs), as the latter did not have any such exposure. However, the second and third round effects of the declining economic activities and the global recession are now impacting all PICs through real channels rather than through financial channels,

The real channels are commodity prices, trade volumes, tourism and remittances (Asian Development Bank 2009a). Due to decreases in commodity prices consequent to lower demand for them in advanced countries, Papua New Guinea (PNG), which exports mineral and non-mineral products, and Solomon Islands which exports timber, are presently experiencing fall in incomes. In addition to exporters' incomes, revenues of governments have also been adversely impacted by fall in receipts from export related taxes and royalties. Consequently the negative effects of fall in commodity prices are expected to be substantial as recession gets prolonged.

As regards trade, fall in petroleum prices since the peak price in mid 2008, would benefit the fuel importing PICs. Hence, the negative effects would be relatively modest. However, the fall in incomes and wealth and consequent decrease in the consumption of discretionary goods and services in developed countries would lead to a decline in tourism. The relevant tourism source markets for PICs, namely Australia, Japan, New Zealand and the US are in recession. Tourism traffic has already begun to slow down. Similarly, remittance inflows from the nationals of PICs resident in the advanced countries are expected to register declines, because of rising unemployment or fall in opportunities for overtime work.

Inward remittances are important notably for Samoa and Tonga, and to a lesser extent for Fiji, Kiribati and Tuvalu (World Bank 2006a). Although there are indications that global recession would result in decline in remittances, a report by Asian Development Bank

(2009b) strikes an optimistic note by referring to the resilience shown by remittances in recent years. For example, remittance inflows to PICs rose during 2000 and 2001, and again in 2005 and 2006 despite slowdowns in economic growth in Australia and New Zealand. Further, the implementation of seasonal worker schemes between PICs and Australia and New Zealand is expected to provide a new and steady source of remittance inflows (Asian Development Bank 2009b).

Response to global crisis by PICs has been mixed, as it is influenced by the availability of both domestic resources and international reserves. Only two PICs have some leeway in terms of fiscal space and levels of foreign exchange reserves to launch fiscal stimulus initiatives. They are PNG and Vanuatu, as they are in better financial shape due to accumulation of international reserves thanks to commodity price boom in case of PNG and budget surpluses as a result of prudent budgetary policies in the case of Vanuatu. Other PICs have however been cautious, as they are constrained by the current level of international reserves, fearing that sizeable fiscal deficits would be inflationary, spilling over into demand for imports and exerting excess pressure on exchange markets.

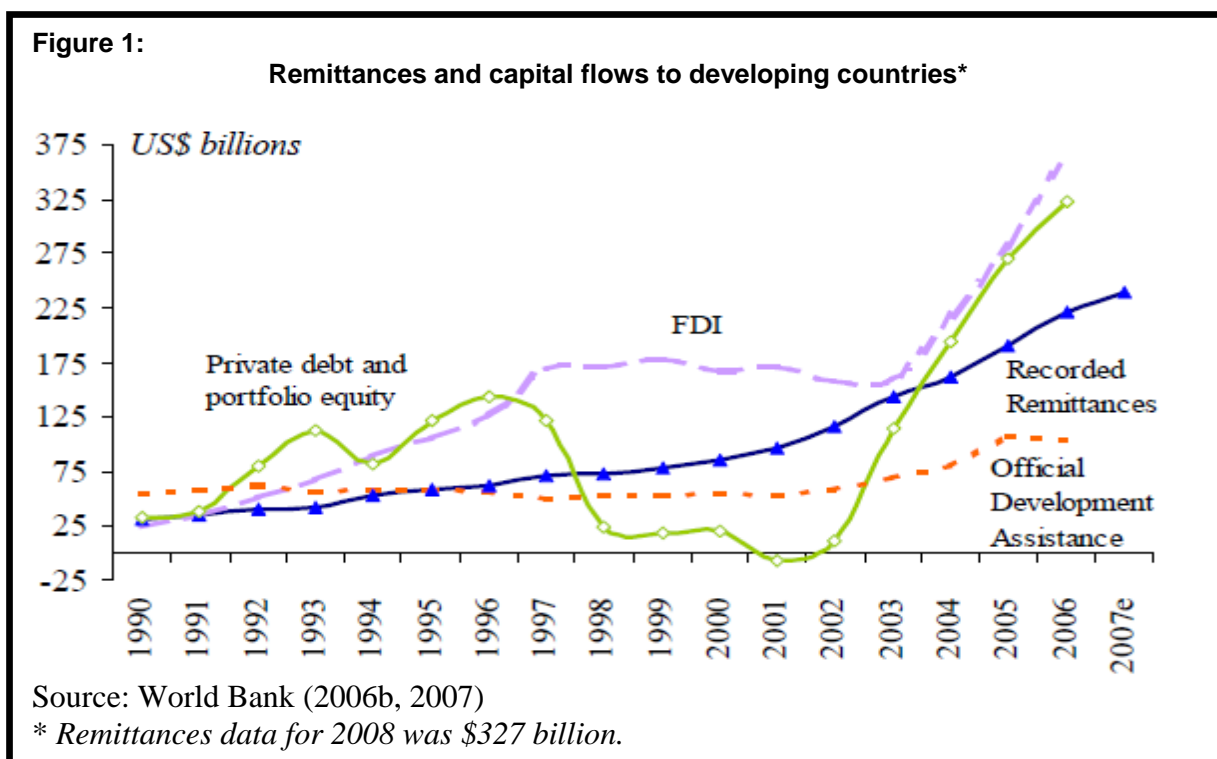

In these circumstances, PICs are conscious of conserving international reserves needs. In the same vein, maintaining and even attracting greater inflows of remittances by offering additional incentives as well as by persuading banks to lower charges on transfer of funds at both points of sending and receiving have been given full attention. Remittance inflows have helped PICs in several ways. Aside from adding to the international reserves and real resources of the country, thereby reducing the inflationary pressures arising out of fiscal deficits, remittance inflows increase the liquidity in the banking system, enabling banking institutions to reduce interest rates as well to provide greater credit to private sector for productive purposes and growth.

The paper seeks to investigate the relationship between economic growth and remittances in Samoa, which averaged about 25 percent of GDP during 2004-2008. This is also the period during which bank lending to private sector also registered a high growth. The indications are that remittance receipts are now increasingly entering the system through

banking channels, improving greater financial intermediation. The latter facilitates transfer of funds to investors in the private sector for investment in productive areas. The paper is organized into five sections. The following section provides a brief review of economic literature on the linkages between and remittances and growth; the third section examines recent trends in remittances to PICs and Samoa. The fourth section outlines the methodology adopted to undertake the empirical study. The fifth section discusses the results of the empirical investigation. The last section presents some conclusions with policy implications.

II. A BRIEF LITERATURE SURVEY

Remittances are defined as private income transfers that take place between family members. In many cases, one or more family members live and work abroad while regularly transferring, or remitting, income back to the remaining family unit in the home country (Chami et al 2006). Remittances have surpassed official development assistance of developing countries (Figure 1).

Remittances flows to developing countries have grown substantially, increasing from \$22 billion in 1985-1989 to \$327 billion in 2008 (Table 1).

Table 1: Remittance, capital inflows to developing countries from 1990 – 2007*

*In 2008, estimated remittance inflow to developing country was \$327billion

Remittances have been playing an important role in developing countries by boosting economic growth and reducing poverty, as well as enabling the recipient families to increase consumption (MacLellan and Mares 2005; Ratha 2007). Their contribution to growth is however dependent upon the scale and intensity of financial sector development. The latter is signified by the presence of deposit accepting banking

institutions and financial deepening. Further, remittances are an important source of external capital for many developing countries, and substantially contribute to poverty reduction (Adams and Page 2003, Ratha 2003, World Bank 2006b). By adding to the stock of international reserves, remittances improve a country's credit worthiness by improving the country-risk rating. This in turn reduces the cost of borrowing money in international markets and enhances its access to international capital markets.

In economies where financial markets are underdeveloped, remittances may alleviate credit constraints and act as a substitute for financial development and growth. However, if remittance inflows are spent on consumption primarily, rather than accumulating as savings or on productive investment, the impact on growth is likely to be minimal. Adams et al (2008) in their studies of remittances effect on spending behavior of households in Ghana finds that remittances when spent just like any other source of income on consumption did not have a significant impact on growth.

Implementation of financial sector reforms, including deregulation of interest rates and encouraging new entrants to the banking sector for allowing greater competition among the banking institutions has facilitated a healthy shift of remittance flows from informal to formal banking arrangements (Browne 2006). As and when remittances are deposited with financial institutions, a cash economy gradually evolves. Consequently, a large number of population would have access to increased credit facilities for education, home mortgages, and small business enterprise (Browne 2006). Shabaz et al (2007), using Pakistan's case concludes that appropriate financial sector reforms would have a positive impact on financial sector development.

Specifically in Pacific islands, three phases of emigrants' motivations behind steady remittances, evolving over their careers have been identified by an IMF study (Browne 2006). In the first phase, remittances are meant for meeting basic consumption needs of families living in home countries; and later the expenditures extend to cover telephones, sound systems computers and outboard motors. The second phase is for human capital investment for the next generation, which includes support schooling in the home country

and later for support for higher education abroad. The next phase focuses on future retirement needs if migrants decide to return home, including long term needs such as real estate purchases and house building as well as business investment purposes (Browne 2006).

Brown and Ahlburg (1999) in their study of Samoa and Tonga have documented that besides through formal channels, remittances sent or contributed through informal channels are sizeable. Maclellan and Mares (2005) point out that migration has become an outlet for many PICs including many small islands states, such as Niue, Kiribati, Tuvalu, Wallis and Futuna. Overall, remittances spent on expenditures beyond daily consumption enhance productive capacities of the economy, thereby contributing to economic growth.

The transaction costs involved in sending remittances to PICs have however been high. The transaction cost of remittance depends on a number of market factors. These include (a) the number of competitors (service providers) in the market, which depends on the size of that particular remittance corridor and on legal regulations; (b) the cost of remittance providers, which depends on the method and technology used; (c) the customer needs and preferences, which may include choices available depending on the required speed, the needs at the destination, as well as the sender's legal status; and (d) the consumers awareness of choices available to them (Ratha and Riedberg 2005).

It has been estimated by Gibson *et al* (2007) that transfer of funds cost about US\$40 million per year. Among the channels used by the remitters in the region, which include Western Union money transfers, bank drafts and automated teller machines (ATM), the latter is the cheapest of all. Ratha and Riedberg (2005) note that transaction costs in remittance transfer can be substantially reduced through the use of ATM technology, which reduces labour costs considerably. A World Bank study (2006) reports that remitting NZ\$100 (UD\$168) to Tonga through channels other than ATM costs 25 to 30 percent of the total remitted. However, ATM technology has yet to become popular.

III. TRENDS IN REMITTANCES IN PACIFIC ISLAND COUNTRIES

Trends in PICs

In the Pacific region, Fiji, Samoa and Tonga receive substantial remittance inflows in absolute terms compared to other PICs. Remittance inflows of Samoa, Tonga and Kiribati account for a large proportion of their respective gross domestic products (Table 2).

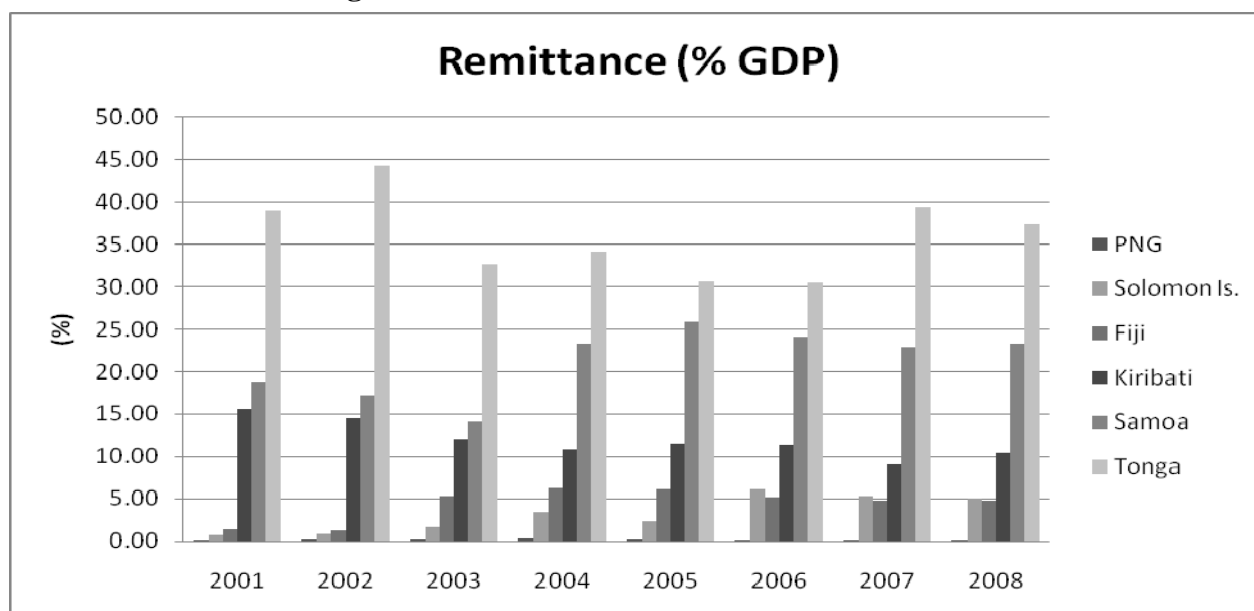

Table 2: PICS: Remittances (US\$ millions): 1970-2008

Figures in parentheses denote percentages to GDP.

Remittances are extremely important to Samoa, whose key indicators are given in Table 4. As noted earlier in regard to developing countries in general, remittances have been providing substantial benefits to Samoa as well. These include financing household consumption as well as schooling of young members of the household. Further, remittances in recent years have been instrumental in providing the much needed stability to annual balance of payments of the country by improving the current account as growing trade imbalances are reduced to a large extent.

Remittances will continue to be the main source of foreign exchange to the Samoan economy. Exports of Samoa have been declining since mid 2008, due to fall in the only manufactured exports, namely automotive harness products for Australian automobile industry following the to scaling down of the Yazaki Samoa. In the context of falling agricultural exports, remittances have been a significant source of support to its foreign exchange earnings.

IV. DATA, MODELING AND METHODOLOGY

Empirical investigation of the nexus between remittances and growth seeks to focus on possible linkages between expenditures out of remittances and GDP. However, in the context of paucity of disaggregated expenditure data in Samoa, our study is constrained to

be simple. We employ the aggregated data on remittances reported on an annual basis by the World Bank (2009).

If remittance inflows are duly deposited by the recipients in the country's banking system, either as additions to savings and current accounts or long term deposits or both, bank's reserves would increase and increases in liquidity would contribute to rise in provision of loans to private sector. We therefore hypothesize that remittances and credit to private sector are positively associated and rise in private sector activities, facilitated by increases in credit, lead to rise in production of goods and services. As the domestic market is small, rise in production of goods and services would result in rise in exports, leading to higher economic growth. The data on private sector credit and GDP data on annual basis, covering a 28-year period (1981-2008), are drawn from *International Financial Statistics* published by International Monetary Fund (2009) and from *World Development Indicators* published by World Bank (2009).

The model is written as follows:

$$RGDP = f(REM, PCR, XGS) \quad (1)$$

Where

RGDP = real GDP in millions of tala;

REM = remittances as percent of GDP;

PRC = credit to private sector as percent of GDP;

XGS = exports of goods and services as percent of GDP;

Bounds testing approach

Since the number of observations is not large enough for estimating a long-run money and output model, we resort to the autoregressive distributed lag (ARDL) procedure, developed by Pesaran et al. (2001). The ARDL bounds testing model is a general dynamic specification, which applies lags of the dependent variable and the lagged and contemporaneous values of the explanatory variables, through which short-run impacts can

be directly assessed and long-run relationship indirectly estimated¹. For econometric analysis, all variables are duly transformed into their natural logs.

An ARDL model of Equation 1 is constructed as follows:

$$\begin{aligned} \Delta LR GDP_t = & \beta_0 + \beta_1 LR GDP_{t-1} + \beta_2 LREM_{t-1} + \beta_3 LPCR_{t-1} + \beta_4 LXGS_{t-1} + \sum_{i=1}^p \alpha_{1i} \Delta LR GDP_{t-i} \\ & + \sum_{i=0}^p \alpha_{2i} \Delta LREM_{t-i} + \sum_{i=0}^p \alpha_{3i} \Delta LPCR_{t-i} + \sum_{i=0}^p \alpha_{4i} \Delta LXGS_{t-i} + \varepsilon_t \end{aligned} \quad (2)$$

There are two steps in examining the relationship between real output, remittances, private credit and exports. First, we estimate Equation (2) by ordinary least squares techniques. Second, the existence of a long-run relationship can be traced by imposing a restriction on all estimated coefficients of lagged level variables equal to zero. Hence, bounds test is based on the F-statistics (or Wald statistics) with the null hypothesis of no cointegration ($H_0 : \beta_1 = \beta_2 = \beta_3 = \beta_4 = 0$) against its alternative hypothesis of a long-run cointegration relationship ($H_1 : \beta_1 \neq \beta_2 \neq \beta_3 \neq \beta_4 \neq 0$).

Since the F-statistics used for this test has a non-standard distribution, Pesaran et al. (2001) have generated two different sets of critical values for given significance levels. The first set assumes that all variable are integrated of order zero, I(0) and the second set assumes all variables are integrated of order one, I(1). If the computed F-statistic is greater than the upper critical bounds value, then the null hypothesis is rejected. In contrast, if the computed F-statistic is smaller than lower critical bounds value, it indicates no long-run relationship between variables. If the computed F-statistic lies between lower and upper bounds values, then the test becomes inconclusive.

Granger causality test

¹ The use of this technique is also based on its advantages over the conventional cointegration procedure. See, for example, Pesaran et al. (2001), Chang et al. (2001), Narayan and Smyth (2005), Akinlo (2006), among others for the advantages and applications of ARDL.

We conduct the Granger causality test in the parsimonious vector error correction model (PVECM) framework to investigate the short-run causality relationship between real output, remittances, private credit and exports. In PVECM framework, we regress the change in variables (both endogenous and exogenous) on lagged deviations and it can be written as follows²:

$$\Delta Z_t = \Pi Z_{t-1} + \Gamma_1 \Delta Z_{t-1} + \Gamma_2 \Delta Z_{t-2} + \dots + \Gamma_{p-1} \Delta Z_{t-p+1} + u_t \quad (3)$$

$$\text{where } \Delta Z_t = [\Delta LR GDP, \Delta LREM, \Delta LPCR, \Delta LXGS]', \quad \Pi = - \left(\mathbf{1}_m - \sum_{i=1}^p A_i \right) \quad \text{and}$$

$$\Gamma_i = - \left(\mathbf{1}_m - \sum_{j=1}^i A_j \right). \text{ For } i = 1, \dots, p-1.$$

Γ reflects the short run effect of the changes in Z_t .

Meanwhile, the (4×4) matrix of $\Pi = (\alpha\beta)'$ contains the speed of adjustment to long-run equilibrium (α) and the long-run information (β) such that the term $\beta' Z_{t-p}$ represents the $(n-1)$ cointegrating vector on the model.

The Granger causality test is conducted by computing the F-statistics (or Wald test) based on the null hypothesis that the set of coefficients (Γ_i) on the lagged values of explanatory variables are not significantly different from zero. If the null hypothesis is rejected, then it is concluded that the explanatory variables cause the dependent variables. If Π is found not significant based on the t-statistics, then both the explanatory and dependent variables do not have a stable relationship in the long run.

V. RESULTS

The results of bound tests are reported in Table 5. The test results reject the null hypothesis of no long-run relationship between real output, remittances, private credit and exports at 1% significance level since the computed F-statistics are found significant in the equation

² Engle and Granger (1987) and Irandoust and Ericsson (2004) provide a comprehensive discussion of this technique.

with LRGDP as the dependent variable. However, the respective computed F-statistics in the equations with other variables as dependent variables are found not significant.

Table 5: Results of Bound Tests

Dependent Variable		Computed F-statistic			
LRGDP		7.7888***			
LREM		1.2965			
LPCR		1.2805			
LXGS		1.4337			
		Pesaran, et al. (2001) ^a		Narayan (2005) ^b	
	Critical Value	Lower bound value	Upper bound value	Lower bound value	Upper bound value
	1 per cent	4.29	5.61	4.614	5.966
	5 per cent	3.23	4.35	3.272	4.306
	10 per cent	2.72	3.77	2.676	3.586

^a Critical values are obtained from Pesaran et al. (2001), Table CI(iii) Case III: Unrestricted intercept and no trend, p. 300.

^b Critical values are obtained from Narayan (2005), Table case III: unrestricted intercept and no trend, p. 10. *, ** and *** indicate significance at 10%, 5% and 1% levels, respectively.

The only one significant long run equation obtained by bounds testing procedure is:

$$LRGDP_t = -58.786 + 2.114LREM^{**} + 3.868LPCR^{**} + 9.954LXGS^{**} \quad (4)$$

$$t = \quad (-2.105) \quad (2.737) \quad (2.781) \quad (3.0150)$$

** indicates significance at 5% level. Figures in parentheses are t-statistics.

In the equation above, we find the coefficients of the explanatory variables have the theoretically expected positive signs. Further, they are also statistically significant. The results confirm that remittances, private credit and exports promote economic growth. As for the magnitudes of coefficients, we observe exports of goods and services have stronger effects on real output than the other two variables, namely private credit and remittances

A number of diagnostic tests were performed. The diagnostic test results show that disturbance terms are normally distributed and serially uncorrelated with homoscedasticity of residuals, confirming the model has a correct functional form. Moreover, the CUSUM and CUSUM of Squares plot show that the parameters of the model are stable over time.

Given the results of bounds test, we proceed to undertake Granger causality tests. Since the Granger causality tests require that all variables in Equation 1 must be integrated of order one, we use two unit root tests, the augmented Dickey and Fuller (ADF) (1979) and Ng and Perron (2001) to examine the order of integration of each variable under study. The results of both unit root tests (Table 6) indicate that all variables are integrated of order one. Table 7 shows the results of long-run and short-run Granger causality tests.

Table 6. Results of unit root tests

Variable	ADF		Ng and Perron	
	Level	First Difference	Level	First Difference
LRGDP	-0.9307 (0)	-4.1269** (0)	-1.8483 (0)	-12.6420** (0)
LREM	-2.1362 (0)	-4.8305** (0)	-4.4507 (0)	-12.9806** (0)
LPCR	-2.8756 (0)	-6.3891** (0)	-10.2536 (0)	-12.1329** (0)
LXGS	-2.6333 (3)	-5.4608** (0)	-5.9232 (0)	-12.5241** (0)

Notes: The ADF critical values are based on Mckinnon. The optimal lag is chosen on the basis of Akaike Information Criterion (AIC). The null hypothesis for both ADF and Ng-Perron tests is a series has a unit root (non-stationary) while the null hypothesis of the KPSS test is does not contain unit root (stationary).

The asterisk ** denotes the rejection of the null hypothesis at the 5% level of significance.

Among the four equations, ECT is statistically significant with the expected negative sign only in the equation with LRGDP, as dependent variable. The results, thus, confirm the result obtained by the bound tests that there is only one cointegrating equation, namely the equation with LRGDP as dependent variable. The linkage runs in only one direction, that is, from remittances, credit to private sector, exports of goods and services to real output.

Table 7: Granger causality test for Samoa

Dependent Variable	F-statistics				ECT (t-statistics)
	Δ LRGDP	Δ LREM	Δ LPCR	Δ LXGS	
Δ LRGDP	-	44.9999***	63.0110***	54.8284***	-0.0395*** (-9.5262)
Δ LREM	1.7986	-	5.6151**	5.2093**	-0.0724 (-1.2865)
Δ LPCR	2.2965	5.8016**	-	11.0208***	-0.0185 (-0.3732)
Δ LXGS	3.7951*	6.1760**	19.4565***	-	-0.0165 (-0.4792)

Note: *, ** and *** indicate significance at 10%, 5% and 1% levels, respectively. Figures in parentheses are t-statistics.

Further, in the short-run we find that there is a bi-directional causality between real output and exports, remittances and exports, remittances and credit to private sector, and credit to private sector and exports, while a unidirectional causality running from both remittances and credit and real output.

The results confirm the hypothesis that remittances play an important role in developing countries, depending upon the scale and intensity of financial sector development by adding liquidity in the banking system, which in turn promotes greater credit to private sector, resulting in rise in growth.

6. Conclusion and Policy Implications

Amongst the PICs, Tonga and Samoa receive large amounts of inward remittances from citizens and residents of their national origin overseas, which are primarily meant for supporting their families and relatives back home. The remittance inflows have been a great support to the island economies as well, by adding to their real resources as well as international reserves. As foreign exchange earnings from traditional commodity exports including copra and processed coconut cream and oil have been falling with the prospects of tourism getting dimmer due to the continuing global economic downturn, remittances have assumed greater importance.

The resilience shown by remittance inflows to PICs has not only been striking but also encouraging. For example, remittance inflows to PICs rose during the short recession in 2000 and 2001, and again in 2005 and 2006, despite slowdowns in economic growth in Australia and New Zealand. Further, the current implementation of seasonal unskilled worker schemes agreed to by and between PICs and Australia and New Zealand is expected to provide a new and steady source of remittance inflows. The PICs have already hailed these initiatives as a major milestone towards the ambitious long-term goal of regional economic integration. Viewed in this context, the role of remittances in economic development of PICs has been receiving a well-deserved attention.

This paper undertook an empirical investigation of the nexus between remittance and economic growth in Samoa during the past 28-year period (1981-2008). The results showed that remittances have helped Samoa to register greater economic growth. Specifically, remittances by adding to the liquidity in the banking system, led to increases in credit to private sector, which in turn resulted in greater economic activities and resultant rise in exports, thereby leading to growth in GDP.

The policy implications are clear:

- the financial sector development is the key to growth as it channels remittance inflows into the banking system;
- decision makers in the government and financial sector should devise appropriate incentive measures to encourage the remittance recipient families to deposit them in financial institutions, which would contribute to accumulation of higher domestic savings and greater resource mobilization;
- incentive measures would include offering higher interest rates for remittances than available for domestic currency deposits, on the lines offered by the South Asian countries attracting deposits from their non-resident nationals; and
- financial institutions should review the current structure of fees and other charges levied on inward remittances at both ends with a view to removing the hurdles that come in the

way of remitting the funds through formal, financial channels for promoting greater flows of resources to developing countries.
